

# <sup>13</sup>C NMR SPECTROSCOPY - kalsi

<sup>13</sup>C NMR spectroscopy has following advantages over <sup>1</sup>H NMR.

- Range of absorption is wide 80-200 ppm relative to TMS. Thus fewer peaks overlap.
- <sup>13</sup>C isotope has low natural abundance ~ 1% (<sup>12</sup>C is 99%) so <sup>13</sup>C-<sup>13</sup>C coupling is negligible and each magnetically non equivalent carbon gives single unsplit peak.
- In proton coupled spectra, the signal for each carbon is split by the protons bonded directly to that C and rule is followed.

e.g:

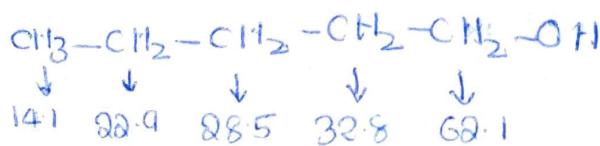

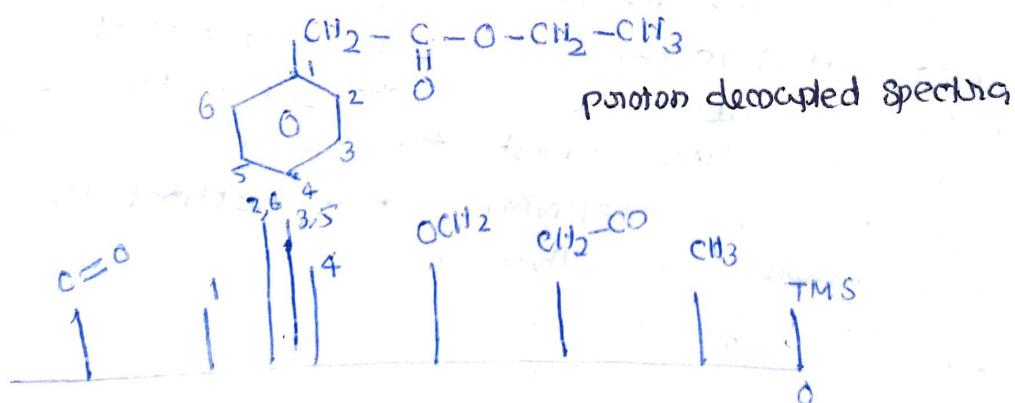

171.1 (s) — C=O      60.6 (d) — OCH<sub>2</sub>

- the areas under the peaks in <sup>13</sup>CNMR may not be proportional to the no of carbon giving rise to the signals.

135.0 (s) — C-1      41.4 (d) — ph-CH<sub>2</sub>  
129.6 (d) — C-2,6      42.8 (s) — CH<sub>3</sub>  
128.8 (d) — C-3,5

- In proton coupled spectra the signal for each carbon is split by the proton bonded directly to that C and rule is followed.

Hydrogen decoupling - Broad band Proton decoupled Spectra Decoupling of protons from the carbons leads to simplification of the spectrum. This will give only sharp peaks for each carbon.

## Multiplicity - 1H decoupling - Noise decoupling

$^{13}\text{C}$  nucleus and  $^1\text{H}$  nucleus both have  $I = \frac{1}{2}$ , but  $^{12}\text{C}$  nucleus is not magnetically active. Since the natural abundance of  $^{13}\text{C}$  is so low  $^{13}\text{C}$ - $^{13}\text{C}$  coupling is very <sup>less</sup>, however  $^{13}\text{C}$ - $^1\text{H}$  coupling can take place to give multiplets in the spectrum.

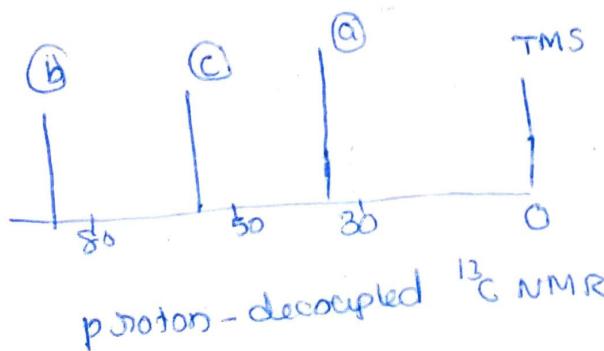

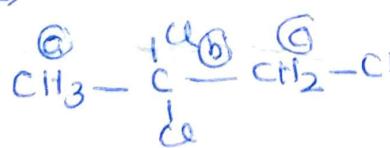

→ Double irradiation of all protons simultaneously and recording  $^{13}\text{C}$  spectrum ~~gives~~ eliminates the complication effect of proton couplings. Thus in this technique a decoupling signal is used, which has  $^1\text{H}$  frequencies spread around 100 MHz and thus is a form of radiofrequency noise. The spectra thus obtained are decoupled or noise decoupled. The sample is simultaneously irradiated with a band of RF radiation that excites OFF-resonance decoupling all the H atoms so no coupling occurs with C nuclei.

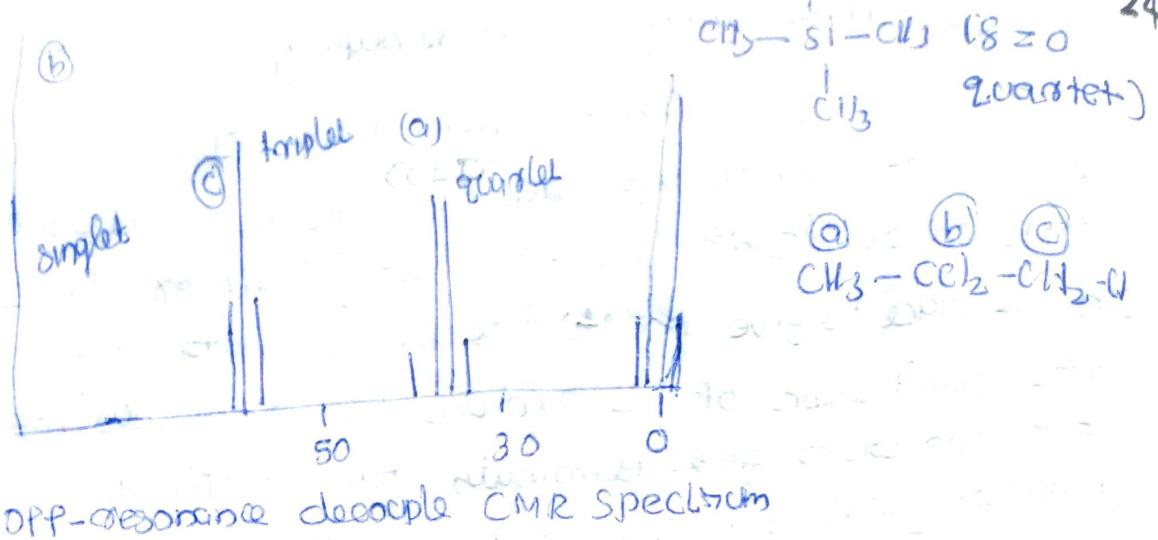

Here the sample is irradiated at a frequency close but not coinciding with the resonance frequency of protons. As a result multiplets becomes narrow, but not removed completely as in fully decoupled spectra. Thus multiplets may still provide useful information without becoming complicated due to overlapping. Thus in off-resonance decoupling  $^{13}\text{C}$  nuclei are split by the protons directly bonded to them only.

$^{13}\text{C}-\text{H}$  coupling possible

$^{13}\text{C}-\text{C}-\text{H}$  or  $^{13}\text{C}-\text{C}-\text{C}-\text{H}$  are not possible

e.g.: 1,2,2-trichloropropane

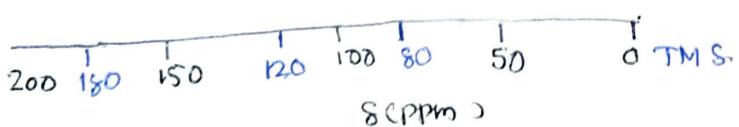

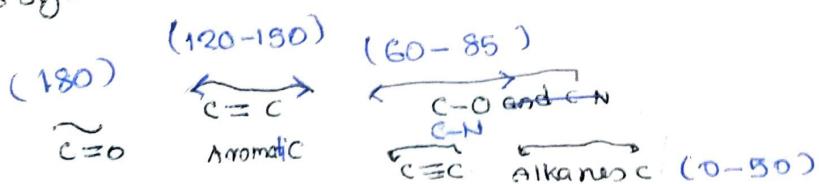

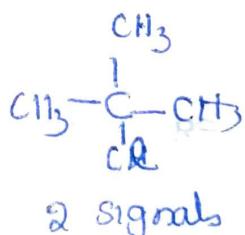

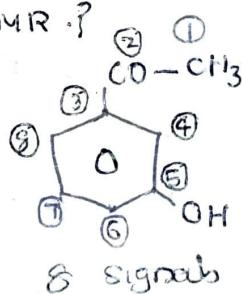

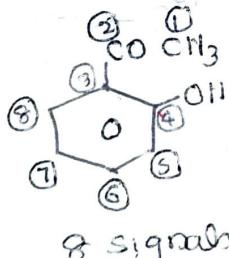

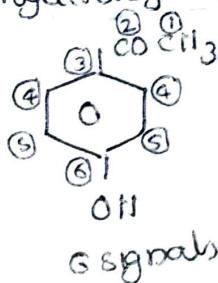

→ The carbons which do not bear protons (e.g.  $\text{CO}$ ) generally have low intensity bcz of long relaxation time. The protons bearing carbons have enhanced line intensity bcz of NOE. Deuterated solvent like  $\text{CDCl}_3$  gives CMR signal which are split by coupling to deuterium.

$$\text{multiplicity} = 2n+1 \\ = 2 \times 1 \times 1 + 1 = 3$$

$\text{CDCl}_3$  gives triplet signal with 1:1:1 ratio

→ chemical shift equivalence

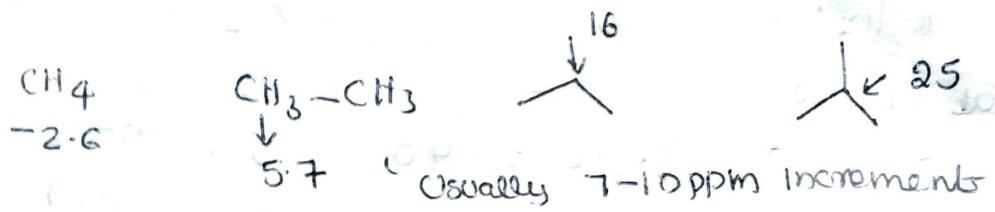

How can you differentiate ortho, meta and para-hydroxy acetophenone from  $^{13}\text{C}$  NMR?

Correlation chart for  $^{13}\text{C}$  chemical shift. Chemical shifts δ (ppm) are related to TMS carbon. Majority of absorptions fall in a range of some 220 ppm downfield of TMS.

25

On moving to quaternary from primary, chemical shift ( $\delta$ ) ppm increases

Chemical shift  $\delta$  can be calculated by eqn for straight chain and branched alkanes

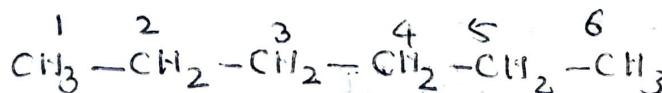

$$\delta_i = -2.6 + 9.1n_\alpha + 9.4n_\beta - 2.5n_\gamma + 0.3n_\delta$$

$n_\alpha$  = no of carbon bonded directly to  $i$ th carbon atom.

$n_\beta$  = " " two bonds away

$n_\gamma$  = " " three bond away

$n_\delta$  = " " four bond away.

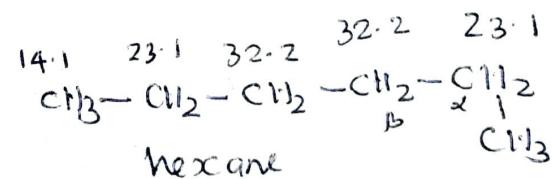

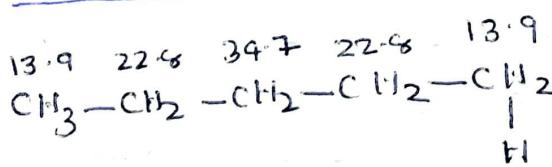

3 signals.

$$\begin{aligned} \text{C-1} &= -2.6 + 9.1 \times 1 + 9.4 \times 1 - 2.5 \times 1 + 0.3 \times 1 \\ &= 13.7 \text{ ppm } (13.9) \end{aligned}$$

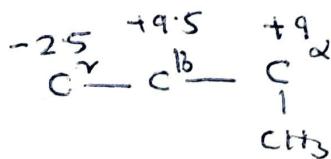

$$\begin{aligned} \text{C-2} &= -2.6 + 9.1 \times 2 + 9.4 \times 1 - 2.5 \times 1 + 0.3 \times 1 \\ &= 22.8 \text{ ppm} \end{aligned}$$

$$\begin{aligned} \text{C-3} &= -2.6 + 9.1 \times 2 + 9.4 \times 2 - 2.5 \times 1 + 0.3 \times 0 \\ &= 31.9 \text{ ppm} \end{aligned}$$

→  $\alpha, \beta$ , and  $\gamma$  effects

Pentane

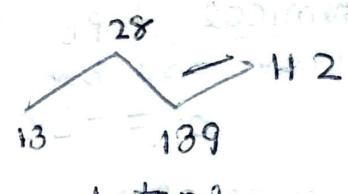

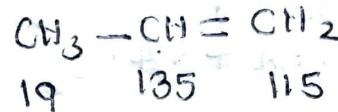

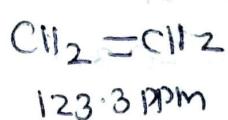

Substituents on  $\alpha, \beta$  carbon generally deshield the  $\delta$  nucleus, but  $\gamma$  position c shields the nucleus.

Hybridization of Carbon

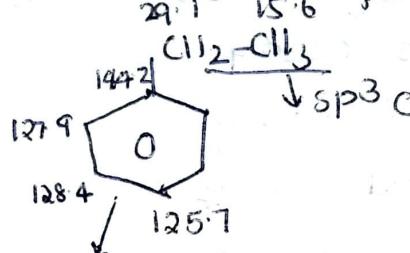

$\text{sp}^3$  hybridized C absorbs at high field - 0-60 ppm from TMS

$\text{sp}^2$  at low field ( $\sim 110-150$  ppm from TMS)

$\text{sp}$  intermediate value (65-90 ppm).  $\text{sp}^2$  C and benzenoid C appear in same region (80-140 ppm)

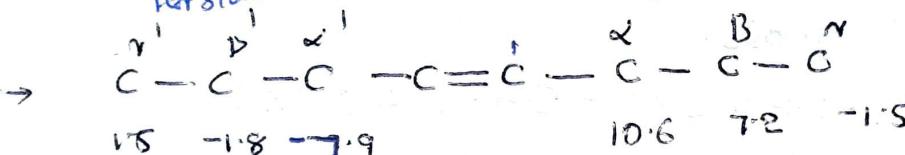

propene

per side

near side

C-1 no substituent near C-1, but substituent on per side  $\alpha'$ ,  $\beta'$ ,  $\gamma'$  of double bonded C-1

$$\text{so } 128.3 + (-7.9 + -1.8 + 1.5) = 115.1$$

$$\delta \text{C}_1 = 115.1$$

C-2  $\alpha$ ,  $\beta$ ,  $\gamma$  substituents on near side

$$128.3 + 10.6 + 7.2 - 1.5 = 139.6$$

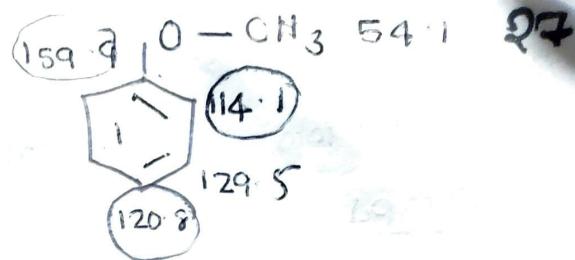

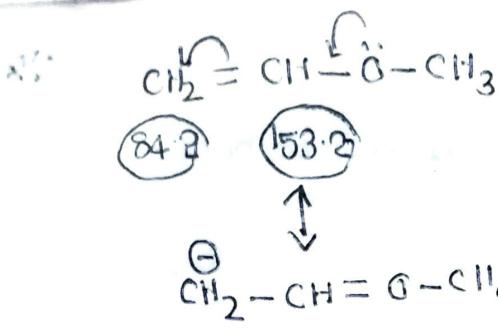

$$\delta \text{C}_2 = 139.6 \text{ ppm}$$

$\alpha$  terminal  $=\text{CH}_2$  absorbs upfield than internal  $=\text{CH}-$

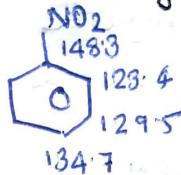

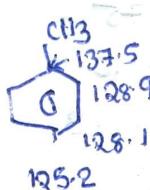

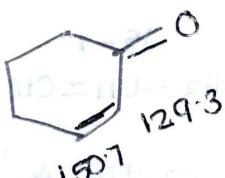

$\rightarrow$  polar effects of substituents on unsaturated carbons

both olefinic and aromatic C come in same region.

→ methoxy group deshields the olefinic and aromatic carbons to which it is attached. The other carbons in the ortho/para positions are shielded due to electron donating ability of oxygen.

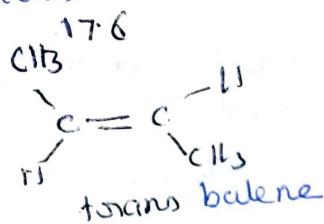

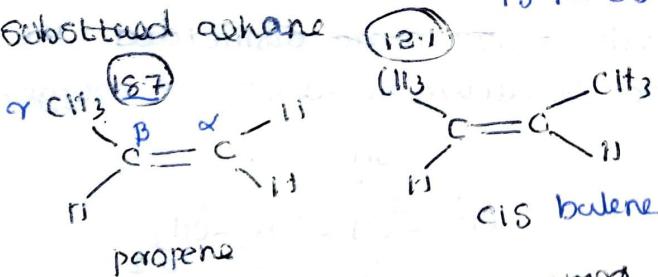

② ipso substitution on the benzene ring deshield the carbon.  
The benzene carbon absorbs at 128.5 ppm. The other correction factor can be applied

<u>sub</u>	<u>C-1</u>	<u>ortho</u>	<u>para</u>
H	O	-4	0
CN	-16	+4	+5
Bz	-5	+3	-2
COOC <sub>2</sub> H <sub>5</sub>	+3	+2	+5
etc.			

### $\alpha$ -effect (Stereostructure of alkenes)

These is upfield shift at the  $\alpha$  carbon in the case of substituted alkanes

$\alpha$ -methyl group in the cis isomer exert  $\alpha$ ,  $\alpha'$  effect  
-5.5 on the others (upfield)

→ presence of double bond

<sup>1</sup>H NMR  $\sim 8$  ppm

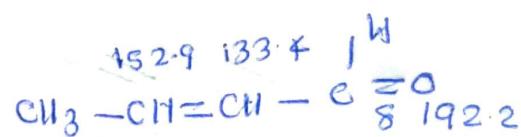

<sup>13</sup>C NMR  $\delta \sim 110 - 150$  ppm

<sup>1</sup>H NMR coupling constant and  $\alpha$ -effect in <sup>13</sup>C NMR are highly useful to deduce the stereostructure of the alkene.

## Carbonyl C

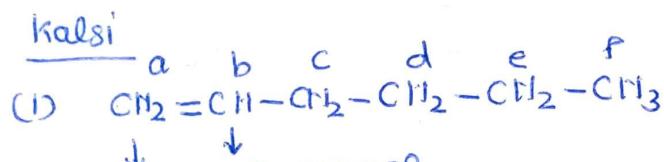

Vary from 150-220 ppm. for carbonyl carbon

<u>Compd</u>	<u><math>\delta</math></u>
ketones	205-220
aldehydes	200-210
carboxylic acid	175-185
1° amide	170-180
C8 ket and anhydride	165-175
2° amide and imide	160-170
$(\text{CH}_3)_2\text{CH}-\text{CH}_2-\overset{\text{II}}{\underset{\text{O}}{\text{C}}}-\text{CH}_3$	$\delta = 207.3$
4-methyl-pentan-2-one	$\delta = 178.3$
$\text{CH}_3\text{CH}_2-\text{CH}_2-\overset{\text{II}}{\underset{\text{O}}{\text{C}}}-\text{OH}$	

crotonaldehyde

## Problems

C-1	e-6	C-5	C-4	C-2	C-3		

In isomer two signals are about 5 ppm upfield so isomer one will be cis isomer.

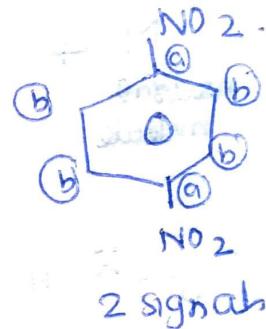

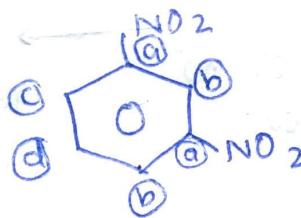

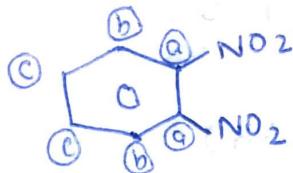

- ⑦ There are 3 isomeric ethers for molecular formula C<sub>4</sub>H<sub>10</sub>O. Name them how many signals were cause in <sup>13</sup>C NMR Spectrum.

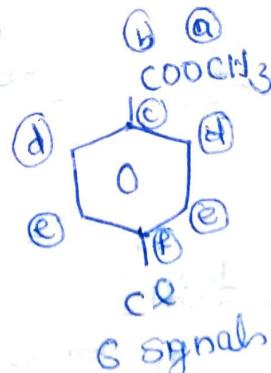

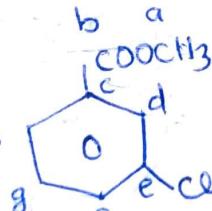

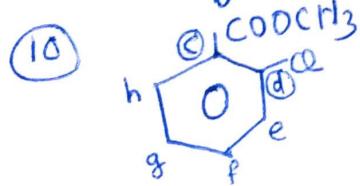

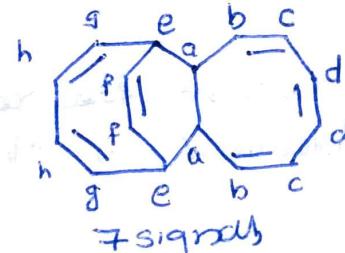

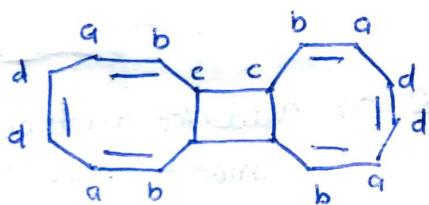

9c C<sub>4</sub>H<sub>10</sub>O

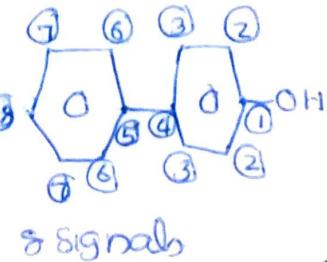

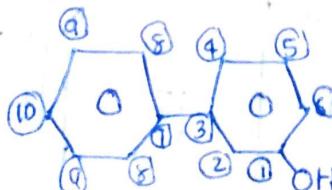

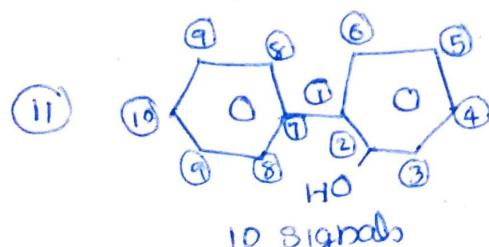

⑧ How can you differentiate?

⑨ In the structures given below, represent the dimer of cyclooctatetraene. The actual structure shows 4 signals in <sup>13</sup>C NMR spectrum. Which is the correct spectrum.

chloro methyl  
benzoate

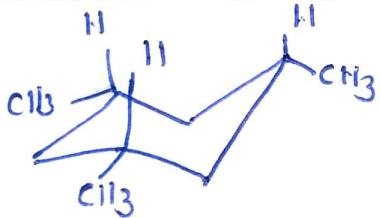

## 59

Carbon-13 NMR Spectroscopy ( $^{13}\text{C}$  NMR) 9447527485  
- Kalsi

$^{13}\text{C}$  NMR is less sensitive than  $^1\text{H}$  NMR due to the following reasons.

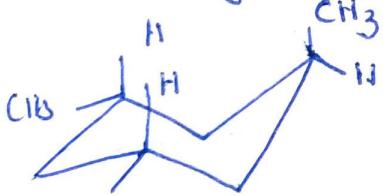

- Most abundant isotope of carbon  $^{12}\text{C}$  (~99%) is not detectable by nuclear magnetic resonance (even no up p and neutron - no magnetic spin), whereas less abundant isotope of C i.e.  $^{13}\text{C}$  ( $\frac{1.1\%}{}$ ) is having a magnetic spin =  $\frac{1}{2}$ .
- Magnetic resonance of  $^{13}\text{C}$  is much weaker. Thus due to only 1% carbon atoms in a sample being the magnetic isotope the sensitivity of  $^{13}\text{C}$  NMR is ↓ed by a factor of 100.
- Gyromagnetic ratio of  $^{13}\text{C}$  being only one-fourth that of a proton, the  $^{13}\text{C}$  resonance frequency is only one-fourth of that for  $^1\text{H}$  NMR (at a given mag field).

### Diastereomers of 1,3,5-trimethylcyclohexane - proton decoupled spectra

1-cis, 3-cis-5-trimethylcyclohexane

(3 signals)

1-cis, 3-trans, 5-trimethylcyclohexane

+ all  $\text{CH}_2$  carbons are equivalent  
+ all  $\text{CH}$  carbons are equivalent  
Total - 3

(8 equatorial methyl + 1 axial methyl + 1  $\text{CH}_2$  groups adjacent to the equatorially sub C + 2  $\text{CH}_2$  groups adjacent to the axially sub C + 8 equatorial C-H carbony + 1 - axial  $\text{CH}$  carbon )

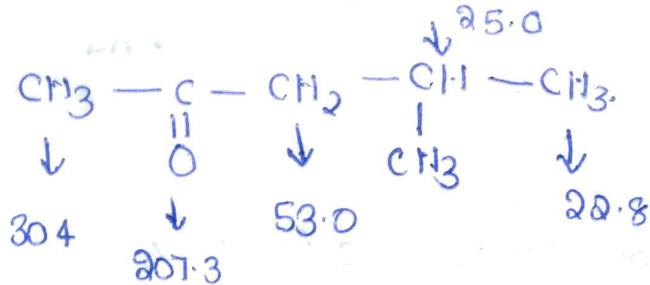

Total - 6

→ chemical shift is 15-20 times greater than protons.

→ Deshielding effect of electronegative moiety

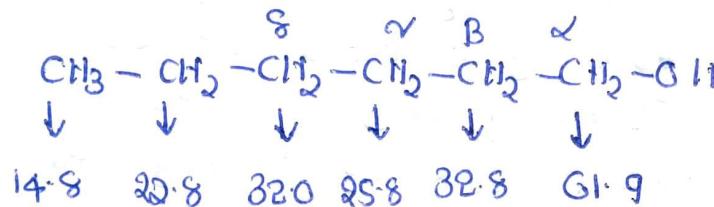

An electronegative substituent, e.g.:  $\text{O}_2\text{N}$ , hetero atom on a carbon atoms brings downfield shift in resonance relative

to a saturated hydrocarbon.

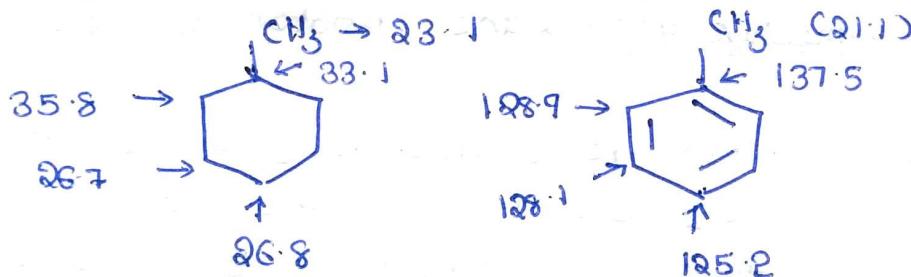

→ a small shielding effect of an electronegative element.

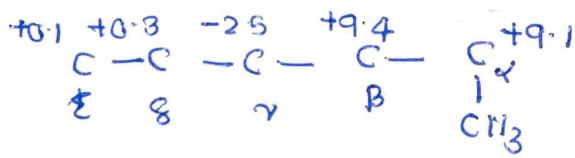

An electronegative element brings deshielding shift for  $\alpha$  and  $\beta$  carbons, but upfield shift for  $\gamma$  carbon.

→ hybridization of C atoms

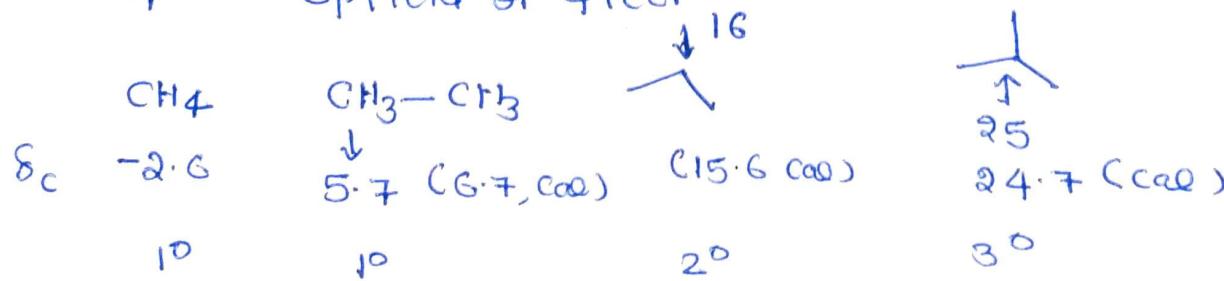

→  $\alpha$ ,  $\beta$ ,  $\gamma$  effects (straight-chain hydrocarbons)

A methyl substituent effect the chemical shift and it is remarkably additive in nature

$\delta_B$  - downfield effect

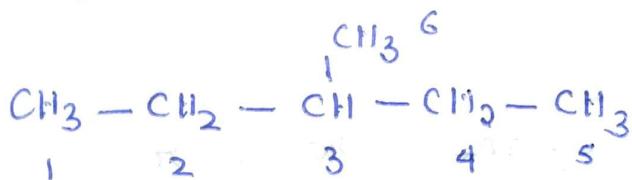

$\gamma$  - upfield effect

$1^\circ \longrightarrow 3^\circ$  (S-increases)

Calculation of chemical shift in straight chain alkanes  
+ branched alkanes

$$\delta_i = -2.6 + 9.1 n_d + 9.4 n_B - 2.5 n_\alpha + 0.3 n_g$$

For C-1 =  $1\alpha + 1B + 2\alpha + 1g$

$$C-1 = -2.6 + 9.1 \times 1 + 9.4 \times 1 + -2.5 \times 2 + 0.3 \times 1 = 11.2 \quad (11.3)$$

For C-2 =  $2\alpha + 2B + 1\alpha$

$$C-2 = -2.6 + 9.1 \times 2 + 9.4 \times 2 + -2.5 \times 1 + -2.5 \times 1 = -29.4 \quad (-29.3)$$

C-2 is a  $2^\circ$  carbon with attached a  $3^\circ$  carbon. Correction for branching [ $2^\circ(3^\circ) = -2.5$ ].

For C-3 =  $3\alpha + 2B$

$$C-3 = -2.6 + 9.1 \times 3 + 9.4 \times 2 + -3.7 \times 2 = 36.1 \quad (36.7)$$

C-3 is a  $3^\circ$  carbon attached  $2^\circ$  atom. Correction for branching

$$3^\circ(2^\circ) = -3.7$$

For C6 =  $1\alpha + 2B + 2\alpha$

$$C-6 = -2.6 + 9.1 \times 1 + 9.4 \times 2 + -2.5 \times 2 + -1.1 \times 1 = 19.2 \quad (18.6)$$

C6 is a  $1^\circ$  carbon attached  $3^\circ$  atom. Correction  $1^\circ(3^\circ) = -1.1$

Corrections for branching ✓

$$1^\circ(3^\circ) = -1.1$$

$$3^\circ(2^\circ) = -3.7$$

$$1^\circ(4^\circ) = -3.4$$

$$3^\circ(3^\circ) = -9.5$$

$$2^\circ(3^\circ) = -2.5$$

$$4^\circ(1^\circ) = -1.5$$

$$2^\circ(4^\circ) = -7.2$$

$$4^\circ(2^\circ) = -8.4$$

$\alpha$ -effect

$\alpha$ -effect has been assigned the value (-2.5) which is the weighted average for open chain conformers. A  $\alpha$  carbon could be either gauche or anti to the

62

resonating carbon and the ratio of the conformer may differ from molecule to molecule.

### Functionalised hydrocarbons

Compared to  $\alpha$ -effect exerted by the replacement of a proton by  $\text{CH}_3$ , the  $\beta\alpha$ -effect exerted by polar substituents are quite large due to inductive effect.

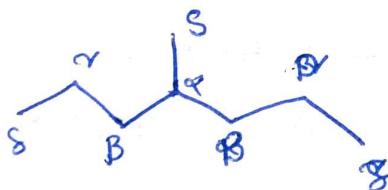

- + 18.8 ← value for methyl carbon of propane
- + 31.0 ← value for terminal  $\alpha$ -Cl
- 4.0 ← Value for  $\alpha$ -Cl

$$42.8 \quad \text{Observed value } 8-42.$$

$$\begin{array}{c} 25.2 + 11 = 36.2 \\ \uparrow \qquad \qquad \qquad \beta \\ \text{Cl}_2-\text{CH}_2-\text{CH}_2-\text{CH}_2-\text{CH}_2-\text{Cl} \\ \downarrow \qquad \qquad \qquad \downarrow \\ 13.4 + 0 = 13.4 \qquad \qquad \qquad 13.4 + 31 = 44.4 \\ S \qquad 25.2 - 4 = 21.2 \qquad \qquad \qquad \alpha \end{array}$$
